# **Congratulations! You passed!**

1 / 1 points	1.	Which notation would you use to denote the 3rd layer's activations when the input is the 7th example from the 8th minibatch? $a^{[3]\{7\}(8)}$ $a^{[8]\{7\}(3)}$ $a^{[8]\{3\}(7)}$ $a^{[3]\{8\}(7)}$ Correct	
1 / 1 points	2.	Which of these statements about mini-batch gradient descent do you agree with?  Training one epoch (one pass through the training set) using mini-batch gradient descent is faster than training one epoch using batch gradient descent.  You should implement mini-batch gradient descent without an explicit for-loop over different mini-batches, so that the algorithm processes all mini-batches at the same time (vectorization).  One iteration of mini-batch gradient descent (computing on a single mini-batch) is faster than one iteration of batch gradient descent.	
1 / 1 points	3.	Why is the best mini-batch size usually not 1 and not m, but instead something inbetween?  If the mini-batch size is 1, you end up having to process the entire training set before making any progress.  Un-selected is correct  If the mini-batch size is m, you end up with batch gradient descent, which has to process the whole training set before making progress.	

# If the mini-batch size is m, you end up with stochastic gradient descent, which is usually slower than mini-batch gradient descent. Un-selected is correct If the mini-batch size is 1, you lose the benefits of vectorization across examples in the mini-batch. Correct

Suppose your learning algorithm's cost J, plotted as a function of the number of iterations, looks like this:

1 / 1 points

Which of the following do you agree with?

compthing is wrong

If you're using mini-batch gradient descent, this looks acceptable. But if you're using batch gradient descent, something is wrong.

## Correct

Whether you're using batch gradient descent or mini-batch gradient descent, this looks acceptable.
 If you're using mini-batch gradient descent, something is wrong. But if you're using batch gradient descent, this looks acceptable.
 Whether you're using batch gradient descent or mini-batch gradient descent,

5. Suppose the temperature in Casablanca over the first three days of January are the same:

1 / 1 points Jan 1st:  $\theta_1 = 10^{\circ} C$ 

Jan 2nd:  $\theta_2 10^o C$ 

(We used Fahrenheit in lecture, so will use Celsius here in honor of the metric world.)

Say you use an exponentially weighted average with  $\beta=0.5$  to track the temperature:  $v_0=0, v_t=\beta v_{t-1}+(1-\beta)\theta_t$ . If  $v_2$  is the value computed after day 2 without bias correction, and  $v_2^{corrected}$  is the value you compute with bias correction. What are these values? (You might be able to do this without a calculator, but you don't actually need one. Remember what is bias correction doing.)

- $v_2 = 10, v_2^{corrected} = 10$
- $v_2 = 10, v_2^{corrected} = 7.5$
- $v_2 = 7.5, v_2^{corrected} = 7.5$
- $v_2 = 7.5, v_2^{corrected} = 10$

Correct

6. Which of these is NOT a good learning rate decay scheme? Here, t is the epoch number.

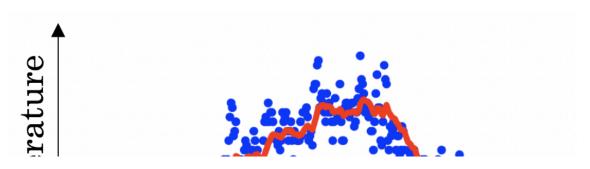

1 / 1 points

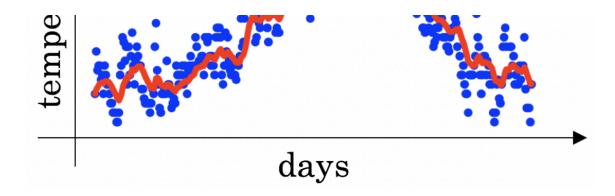

- $\bigcirc \quad \alpha = {}^{1}_{\sqrt{t}} \alpha_0$
- $\bigcirc \quad \alpha = 0.95^t \alpha_0$
- $\alpha = e^t \alpha_0$

Correct

- $\bigcirc \quad \alpha = {}^{1}_{1+2*t} \ \alpha_0$
- 7. You use an exponentially weighted average on the London temperature dataset. You use the following to track the temperature:  $v_t = \beta v_{t-1} + (1-\beta)\theta_t$ . The red line below was computed using  $\beta = 0.9$ . What would happen to your red curve as you vary  $\beta$ ? (Check the two that apply)

1 / 1 points

Decreasing  $\beta$  will shift the red line slightly to the right.

**Un-selected is correct** 

Increasing  $\beta$  will shift the red line slightly to the right.

### Correct

True, remember that the red line corresponds to  $\beta=0.9$ . In lecture we had a green line \$\$\beta=0.98\$) that is slightly shifted to the right.

Decreasing  $\beta$  will create more oscillation within the red line.

# Correct

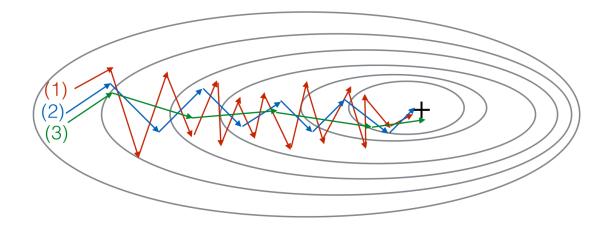

True, remember that the red line corresponds to  $\beta=0.9$ . In lecture we had a yellow line \$\$\beta=0.98\$ that had a lot of oscillations.

Increasing  $\beta$  will create more oscillations within the red line.

**Un-selected is correct** 

# **8** Consider this figure:

1 / 1 points

These plots were generated with gradient descent; with gradient descent with momentum ( $\beta$  = 0.5) and gradient descent with momentum ( $\beta$  = 0.9). Which curve corresponds to which algorithm?

10. Which of the following statements about Adam is False?

We usually use "default" values for the hyperparameters  $\beta_1,\beta_2$  and  $\varepsilon$  in Adam ( $\beta_1=0.9,\beta_2=0.999,$   $\varepsilon=10^{-8}$ )

Adam should be used with batch gradient computations, not with mini-

1 / 1 points

	batches.
Corr	ect
	The learning rate hyperparameter $\alpha$ in Adam usually needs to be tuned. Adam combines the advantages of RMSProp and momentum
